

Day 1 – AI Learning Summary

- AI is a broad term for software that can do “smart” tasks like understanding text, images, or speech.
- An LLM (Large Language Model) is a type of AI focused on language; it predicts text token by token based on patterns from training data.
- ChatGPT, Claude, and Copilot are apps built on top of LLMs.
- A token is a small chunk of text (part of a word, a word, symbol, space, or code piece), not always a full word or sentence.
- You don't control token splitting; a tokenizer decides it using its vocabulary and frequency rules (e.g., “unbelievable” → “un” + “believ” + “able”).
- A prompt is the input or instruction you give to the AI; clearer prompts produce better and more useful answers.
- The context window is the AI's short-term memory, measured in tokens; it includes your messages and the AI's replies.
- When the conversation gets too long or too much code is pasted, older context falls out of the context window and the AI can forget it.
- Temperature controls creativity: low = strict and predictable (best for code), high = more creative but riskier.
- The right mindset: AI is a tool; you must guide it with good prompts and always review and verify its output.
